

# Mincut Placement with FM Partitioning featuring Terminal Propagation

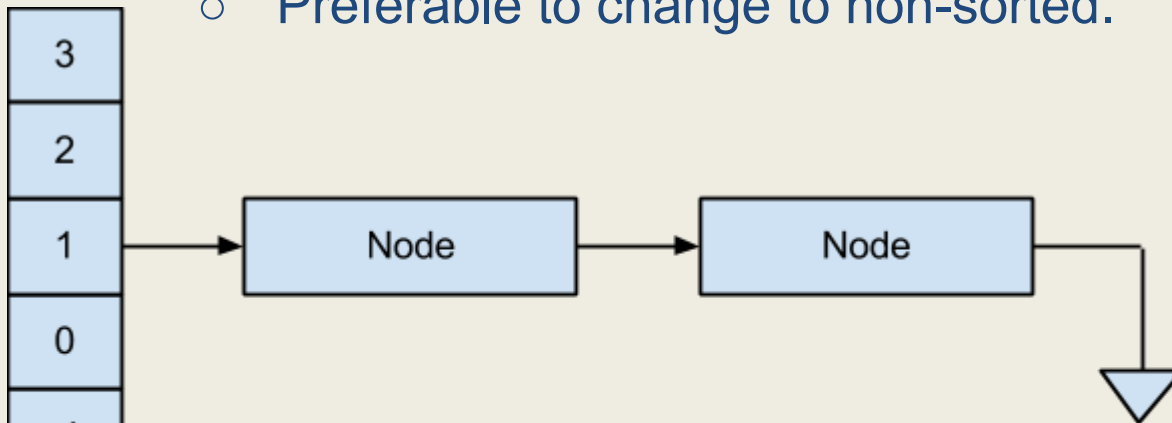

Brett Wilson  
Lowe Dantzler

# Project Overview

- Perform Mincut Placement using the FM Algorithm to perform partitioning.
- Goals:
  - Minimize wire length for placement
  - Minimize cut size between partitions
- Implementation Evaluation Metrics:
  - Wirelength with and without Terminal Propagation
  - Runtime with and without TP
  - Effect of TP window "Dead Zone" on result

# FM Algorithm

- Node and Net information stored in a C++ map (binary tree structure)
- Buckets implemented as a C++ vector of sorted, singly-linked lists.
  - Preferable to change to non-sorted.

## Gain Computations

- $FS(x) = \#$  Nets containing  $x$  as the only cell in partition 1
- $TS(x) = \#$  Nets containing  $x$  where all cells are in partition 1.
- $Gain(x) = FS(x) - TS(x)$

# FM Algorithm

Area Constraints: 50/50 +/- 5% by default

The 3 FM bipartition methods are very similar, but have important distinctions

- Bipartition whole design
  - Continues run until there is a pass with 0 gain.
- Bipartition subset (no TP)
  - Continues run until there is a pass with 0 gain.
  - Ignores nodes not in the current subset.
- Bipartition subset with TP
  - Continues run until there is a pass with 0 gain OR the gain for a pass is less than or equal to the netGain for a pass.
  - Ignores nodes not in the current subset or the propagated terminals

# FM Standalone Results

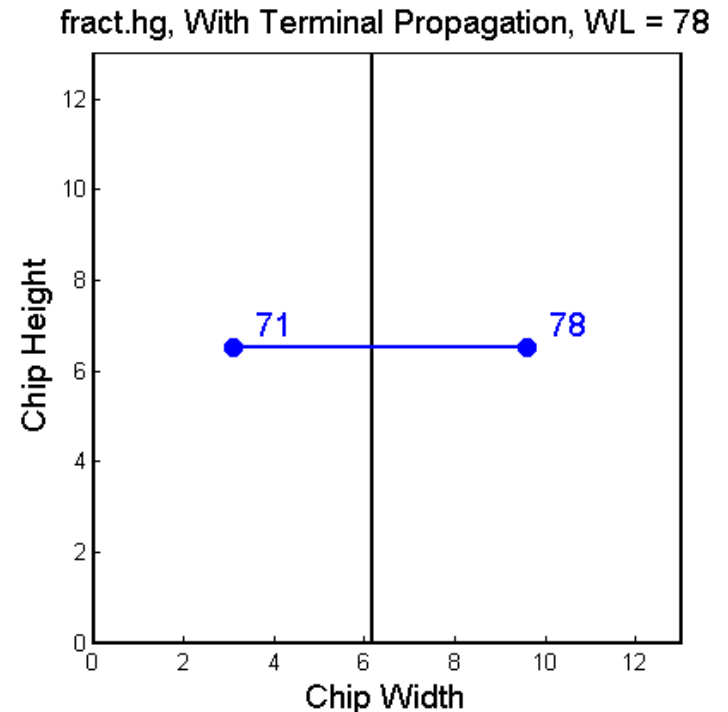

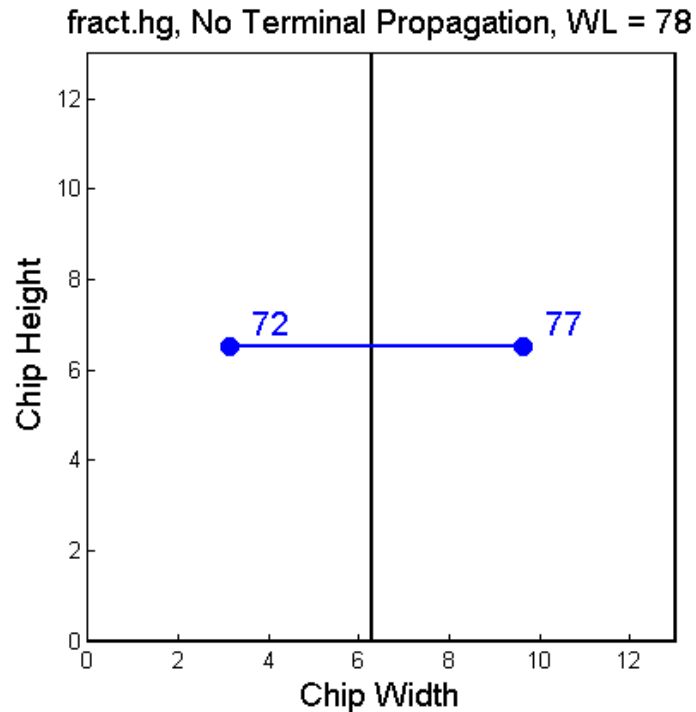

| Netlist   | Nodes  | Nets   | Max Degree |
|-----------|--------|--------|------------|
| fract     | 149    | 148    | 7          |
| ibm01     | 12753  | 14112  | 39         |
| industry2 | 12638  | 13420  | 12         |
| ibm10     | 69430  | 75197  | 137        |
| ibm18     | 210613 | 201921 | 97         |

| Netlist   | Runs | Avg # Passes | Avg Initial Cutsizes | Avg Final Cutsizes | Avg Gain |
|-----------|------|--------------|----------------------|--------------------|----------|
| fract     | 20   | 4.5          | 99.1                 | 12.1               | 87       |
| ibm01     | 10   | 11.7         | 9184.5               | 1376.6             | 7807.9   |
| industry2 | 10   | 18.6         | 8090.4               | 620.9              | 7469.5   |
| ibm10     | 3    | 24.33        | 50705.67             | 6637.67            | 44068    |
| ibm18     | 1    | 29           | 139237               | 34502              | 104735   |

# Placement Assumptions

- Placement done by Mincut placement, using Breadth First Recursive Bisection.
  - Done with and without terminal propagation (TP).
  - When terminal propagation was used, the default "Dead Zone Window," or  $A$ , was 0.3.
  - I.e. 30% of the partition dimension being split.
- Partition area treated the same as cell count, corresponding to the following.
  - Cells are soft, to some extent.
  - Recursion only goes so deep: down to some maximum number of cells per partition. Thus there will be room for an ILP or other floorplan solver to fit the cells to the area.

# Placement Algorithm: Recursive Bisection (1)

Recursive bisection makes a breadthwise traversal of the existing partitions (i.e. as nodes in a binary tree).

The dots in the figures are node clusters, with their number shown. Wire Length (WL) is measured as the sum of the half perimeter bounding boxes (HPBB).

# Recursive Bisection (2)

fract.hg, No Terminal Propagation, WL = 188.5

fract.hg, With Terminal Propagation, WL = 159.5702

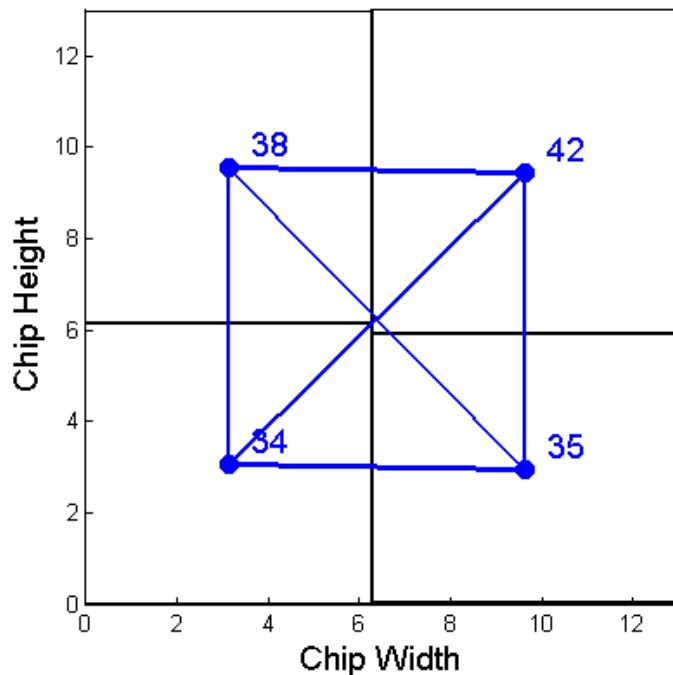

Here a 0.45 to 0.55 area balance is being used, by the FM partitioner.

# Recursive Bisection (3)

fract.hg, No Terminal Propagation, WL = 228.0745

fract.hg, With Terminal Propagation, WL = 195.8706

The area balance is enforced as much as possible, but sometimes it cannot be.  
 $35 / 77 \sim 0.43$

# Recursive Bisection (4)

fract.hg, No Terminal Propagation, WL = 266.8743

fract.hg, With Terminal Propagation, WL = 229.9412

Without TP, the 18 cell cluster has connection(s) at the 42 cell cluster, farthest away.

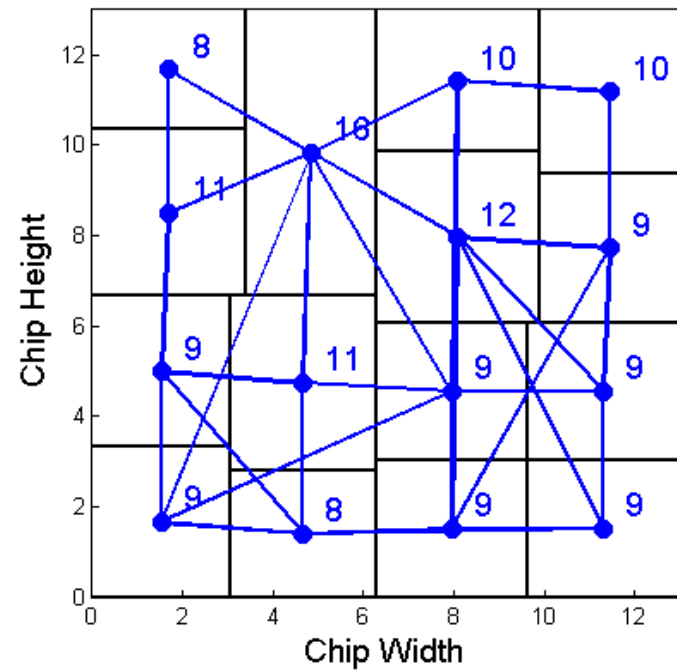

With TP, the corresponding cluster does not have the same distant connection(s).

# Effect of TP (1)

fract.hg, No Terminal Propagation, WL = 487.0277

fract.hg, With Terminal Propagation, WL = 422.9681

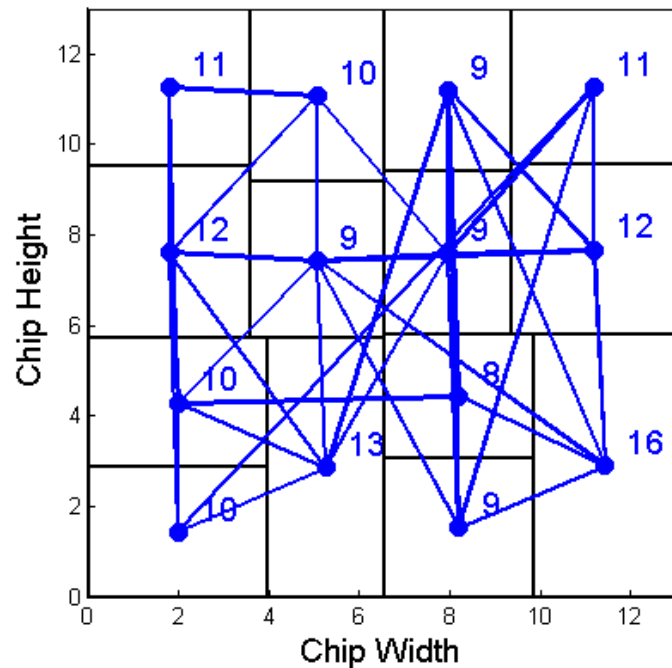

fract.hgr circuit used here, partitioning down to a maximum cell count of 16.

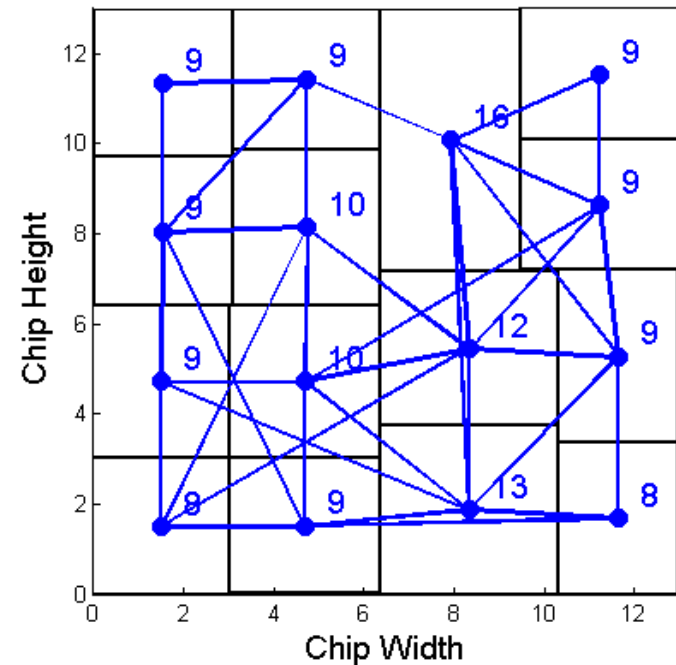

(0.45, 0.55) are constraints used by FM partitioner.

# fract.hgr, Effect of TP (2)

fract.hg, No Terminal Propagation, WL = 463.2465

fract.hg, With Terminal Propagation, WL = 432.0703

Notice overall appearance of connections, for each case.

# fract.hgr, Effect of TP (3)

fract.hg, No Terminal Propagation, WL = 508.7945

fract.hg, With Terminal Propagation, WL = 386.2861

The drawn connections are meaningful. They are from the MSTs of the net, which is a good approximation of the wirelength for routing.

Recall however that the shown wirelength is for the sum of the HPBBs.

# fract.hgr, Effect of TP (4)

fract.hg, No Terminal Propagation, WL = 484.912

fract.hg, With Terminal Propagation, WL = 397.5012

Note the difference in wire length, measured by HPBB.

# Benchmarks

| Netlist   | Nodes  | Nets   | Max Degree | Max Cells | Square Area |
|-----------|--------|--------|------------|-----------|-------------|
| fract     | 149    | 148    | 7          | 16        | 169         |
| ibm01     | 12753  | 14112  | 39         | 512       | 12769       |
| industry2 | 12638  | 13420  | 12         | 512       | 12769       |
| ibm10     | 69430  | 75197  | 137        | 2048      | 69696       |
| ibm18     | 210613 | 201921 | 97         | 4096      | 210681      |

Max Cells was decided, to keep the resulting partition areas large, so that limited cell softness, or even cell hardness, would not be a problem for the floorplanner. Giving floorplanner "room."

Square area is the minimum square area needed, assuming cells are hard 1 x 1 (not an assumption we used). This is a number to shoot for.

# Wire Length Results

| Table: Wire Length, No TP   |             |             |                |                  |
|-----------------------------|-------------|-------------|----------------|------------------|
| Circuit                     | Sample Size | Sample Mean | Sample Std Dev |                  |
| fract                       | 12          | 469         | 23             |                  |
| ibm01                       | 6           | 318533      | 30628          |                  |
| industry2                   | 3           | 239342      | 29036          |                  |
| ibm10                       | 1           | 4321970     | -              |                  |
| ibm18                       | -           | -           | -              |                  |
|                             |             |             |                |                  |
| Table: Wire Length, With TP |             |             |                |                  |
| Circuit                     | Sample Size | Sample Mean | Sample Std Dev | Avg Decrease (%) |
| fract                       | 12          | 415         | 26             | 12               |
| ibm01                       | 6           | 264808      | 31129          | 17               |
| industry2                   | 3           | 200347      | 10516          | 16               |
| ibm10                       | 1           | 3714070     | -              | 14               |
| ibm18                       | -           | -           | -              | -                |

Notice wire length improvement.

# Run Time Results \*

| Table: Run Time (Seconds), No TP |             |             |                |
|----------------------------------|-------------|-------------|----------------|
| Circuit                          | Sample Size | Sample Mean | Sample Std Dev |
| fract                            | 12          | 0.178       | 0.241          |
| ibm01                            | 6           | 584         | 115            |
| industry2                        | 3           | 2427        | 348            |
| ibm10                            | 1           | 12649       | -              |
| ibm18                            | -           | -           | -              |

  

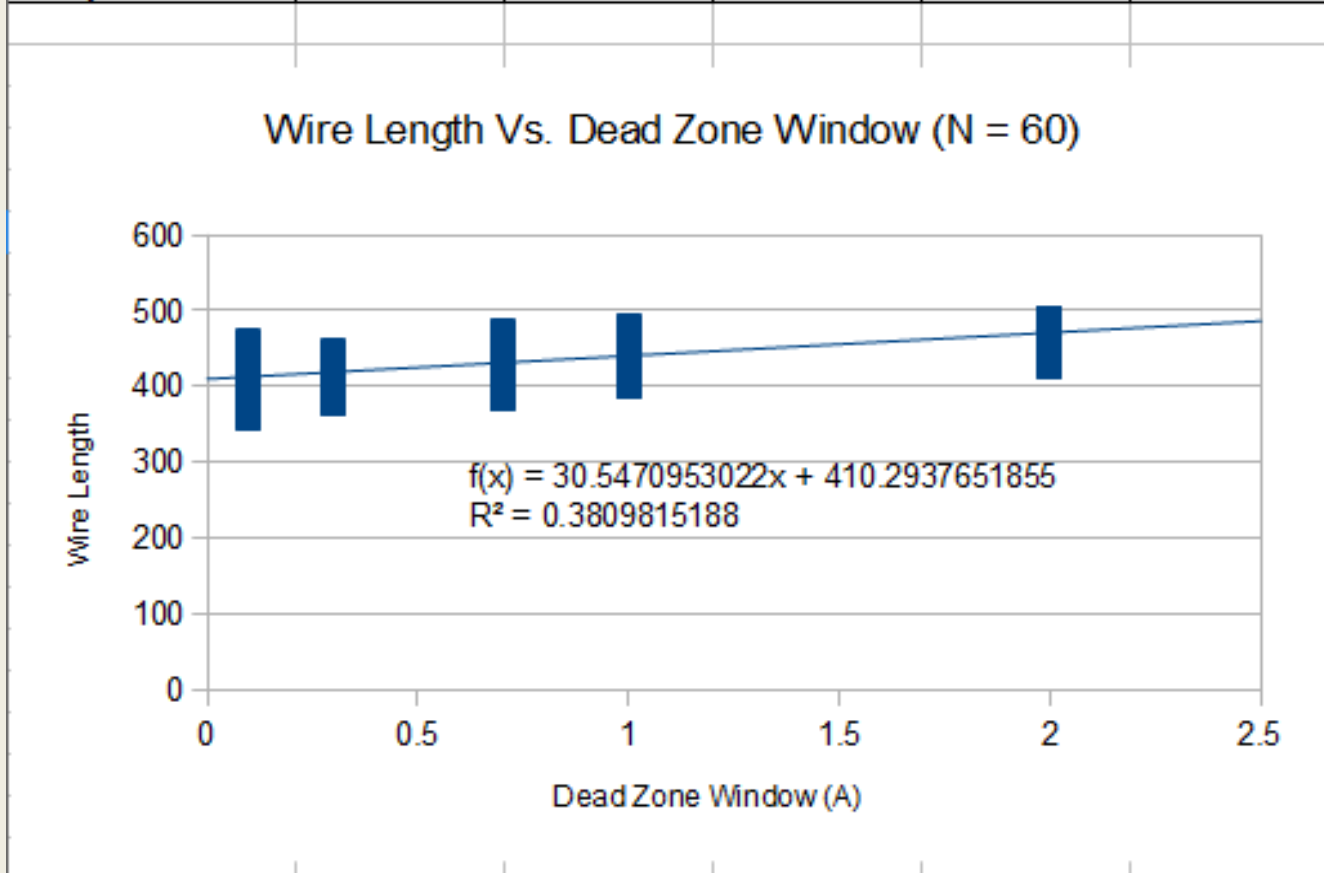

| Table: Run Time (Seconds), With TP |             |             |                |                  |
|------------------------------------|-------------|-------------|----------------|------------------|
| Circuit                            | Sample Size | Sample Mean | Sample Std Dev | Avg Increase (%) |
| fract                              | 12          | 0.087       | 0.028          | -51              |
| ibm01                              | 6           | 473         | 78             | -19              |
| industry2                          | 3           | 3368        | 2373           | 39               |
| ibm10                              | 1           | 8574        | -              | -32              |
| ibm18                              | -           | -           | -              | -                |

\* Some results are for different machines. These are preliminary results, which suggest a general trend only. The general trend is the opposite of what was expected.

# Effect of Dead Zone Window (A)

| n = 12         | A = 0.1 | A = 0.3 | A = 0.7 | A = 1.0 | A = 2.0 |
|----------------|---------|---------|---------|---------|---------|
| Sample Mean    | 417.471 | 415.148 | 422.413 | 452.379 | 469.302 |
| Sample Std Dev | 30.297  | 22.174  | 28.635  | 26.711  | 21.438  |

# Conclusion

- Terminal Propagation has positive impact on wirelength.
- To explain runtime results for non-TP vs. TP, more investigation is needed.
- The best "Dead Zone Window" for terminal propagation is  $\sim 0.3$ , which is similar to what was used in the text book example.
